

Software Quality Assurance Group 28 Test Plan

Organization:

Our test cases are currently stored in our Test Cases directory in separate folders of inputs and outputs for each function. When we move on to coding our front end, we will be creating a test harness for these cases, with a separate program for testing each aspect of the system. This way, each individual function can be tested as a unit before we expand our test suite into integrated or system tests.

Test Formatting:

Each test case is planned to be a shell script that automatically executes commands through the program's front end command line interface. This formatting ensures that the way our program receives input is the same way a user would input it, meaning that the way tests are executed should never be the cause of an error. This, along with nearly everything in our test plan, is still subject to change if a more time efficient method of executing them presents itself.

Output Organization:

Our test program will not only print output to console, but also each one will create a file in which it will store outputs so that they can be checked against later. Then, once we correct whatever issues present themselves through testing, we will have old outputs saved through this system to check against when running tests again.
